

Memory timescale does not explain whether reward history becomes behavior

● neural history readout ■ behavioral history expression

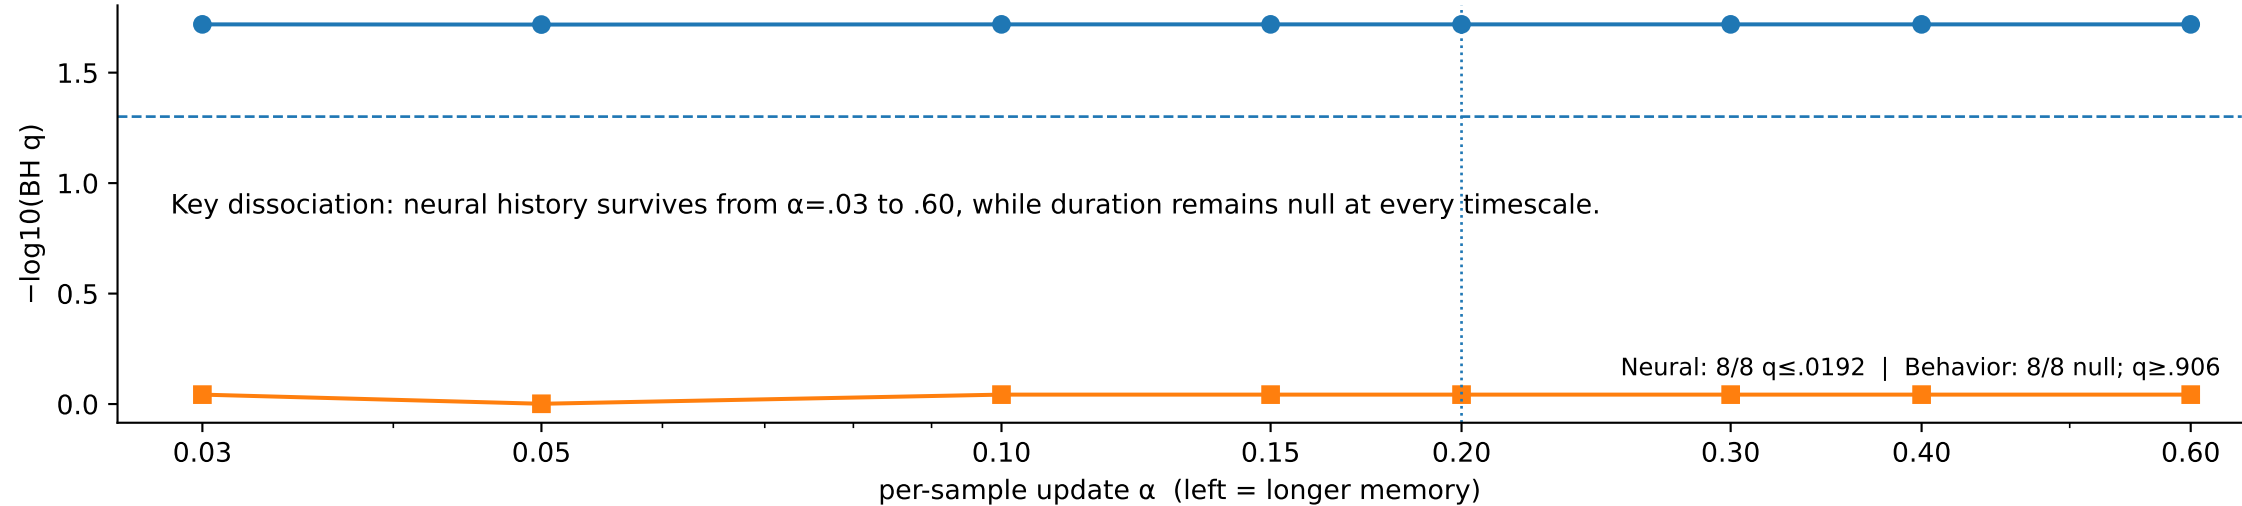

A Natural 100E/20E

B QE: same current 100E, different prior EE/QE history

C VTA stimulation history (Stim13)

Sensitivity scan; $\alpha = .20$ remains the frozen cross-task primary value. BH correction is within endpoint across scanned α values. QE behavioral history remains provisional rather than promoted.
