

Current reward identity shapes apparent behavioral history slopes, but a universal deep-reference gate is not established

A Common-support behavioral interaction

B Termination-hazard sensitivity

C Local-history adjudication

D After residualizing recent history: all null

Interpretation: the common-support current-identity interaction is real enough to warrant analysis, but it is not a universal deep-reference gate.

Natural is the most supportive; QE is underpowered; Stim13 is especially sensitive to local-history specification. Hazard estimates are sensitivity analyses, not the primary small-cluster inference.

Primary $\alpha=.20$ tests use within-animal common support, animal fixed effects, session-progress controls and exact cluster wild sign-flips.
